A stack is an Abstract Data Type *ADT*, commonly used in most programming languages. It is named stack as it behaves like a real-world stack, for example – a deck of cards or a pile of plates, etc.

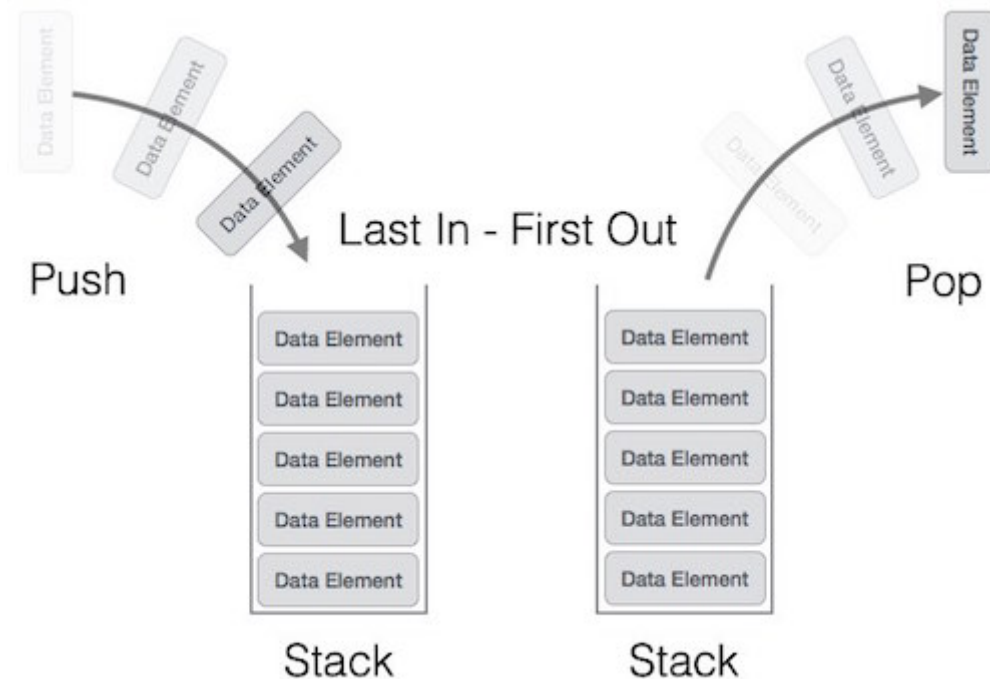

A real-world stack allows operations at one end only. For example, we can place or remove a card or plate from the top of the stack only. Likewise, Stack ADT allows all data operations at one end only. At any given time, we can only access the top element of a stack.

This feature makes it LIFO data structure. LIFO stands for Last-in-first-out. Here, the element which is placed *inserted or added* last, is accessed first. In stack terminology, insertion operation is called **PUSH** operation and removal operation is called **POP** operation.

Stack Representation

The following diagram depicts a stack and its operations –

A stack can be implemented by means of Array, Structure, Pointer, and Linked List. Stack can either be a fixed size one or it may have a sense of dynamic resizing. Here, we are going to implement stack using arrays, which makes it a fixed size stack implementation.

Basic Operations

Stack operations may involve initializing the stack, using it and then de-initializing it. Apart from these basic stuffs, a stack is used for the following two primary operations –

- **push** – Pushing *storing* an element on the stack.
- **pop** – Removing *accessing* an element from the stack.

When data is PUSHed onto stack.

To use a stack efficiently, we need to check the status of stack as well. For the same purpose, the following functionality is added to stacks –

- **peek** – get the top data element of the stack, without removing it.
- **isFull** – check if stack is full.
- **isEmpty** – check if stack is empty.

At all times, we maintain a pointer to the last PUSHed data on the stack. As this pointer always represents the top of the stack, hence named **top**. The **top** pointer provides top value of the stack without actually removing it.

First we should learn about procedures to support stack functions –

peek

Algorithm of peek function –

```
begin procedure peek
    return stack[top]
end procedure
```

Implementation of peek function in C programming language –

Example

```
int peek() {
    return stack[top];
}
```

isfull

Algorithm of isfull function –

```
begin procedure isfull
    if top equals to MAXSIZE
        return true
    else
        return false
    endif
end procedure
```

Implementation of isfull function in C programming language –

Example

```
bool isfull() {  
    if(top == MAXSIZE)  
        return true;  
    else  
        return false;  
}
```

isempty

Algorithm of isempty function –

begin procedure isempty

```
    if top less than 1  
        return true  
    else  
        return false  
    endif
```

end procedure

Implementation of isempty function in C programming language is slightly different. We initialize top at -1, as the index in array starts from 0. So we check if the top is below zero or -1 to determine if the stack is empty. Here's the code –

Example

```
bool isempty() {  
    if(top == -1)  
        return true;  
    else  
        return false;  
}
```

Push Operation

The process of putting a new data element onto stack is known as a Push Operation. Push operation involves a series of steps –

- **Step 1** – Checks if the stack is full.
- **Step 2** – If the stack is full, produces an error and exit.
- **Step 3** – If the stack is not full, increments **top** to point next empty space.
- **Step 4** – Adds data element to the stack location, where top is pointing.
- **Step 5** – Returns success.

If the linked list is used to implement the stack, then in step 3, we need to allocate space dynamically.

Algorithm for PUSH Operation

A simple algorithm for Push operation can be derived as follows –

```
begin procedure push: stack, data
```

```
    if stack is full
        return null
    endif
```

```
    top ← top + 1
```

```
    stack[top] ← data
```

```
end procedure
```

Implementation of this algorithm in C, is very easy. See the following code –

Example

```
void push(int data) {
    if(!isFull()) {
        top = top + 1;
        stack[top] = data;
    } else {
        printf("Could not insert data, Stack is full.\n");
    }
}
```

Pop Operation

Accessing the content while removing it from the stack, is known as a Pop Operation. In an array implementation of pop operation, the data element is not actually removed, instead **top** is decremented to a lower position in the stack to point to the next value. But in linked-list implementation, pop actually removes data element and deallocates memory space.

A Pop operation may involve the following steps –

- **Step 1** – Checks if the stack is empty.

- **Step 2** – If the stack is empty, produces an error and exit.
- **Step 3** – If the stack is not empty, accesses the data element at which **top** is pointing.
- **Step 4** – Decreases the value of top by 1.
- **Step 5** – Returns success.

Algorithm for Pop Operation

A simple algorithm for Pop operation can be derived as follows –

```
begin procedure pop: stack
```

```
    if stack is empty
        return null
    endif
```

```
    data ← stack[top]
```

```
    top ← top - 1
```

```
    return data
```

```
end procedure
```

Implementation of this algorithm in C, is as follows –

Example

```
int pop(int data) {
    if(!isempty()) {
        data = stack[top];
        top = top - 1;
        return data;
    } else {
        printf("Could not retrieve data, Stack is empty.\n");
    }
}
```
